

What is Ontomorph?

Ontomorph is a **patient-owned digital twin platform** that enables developers to build applications around a person's complete digital health representation. The platform provides APIs for managing a health "twin," medical events, biomarkers, clinical decision support, simulations, FHIR interoperability, analytics, and provider workflows.

In other words:

A Digital Twin = A continuously updated digital version of a patient's health.

Everything Ontomorph Offers

1. Twin Core

This is the heart of the platform.

APIs include:

- Create a Digital Twin
- Retrieve Twin
- Update Twin
- List Twins
- Seed demo patient data
- Attach genomic VCF data

Each twin stores:

- DID (Decentralized Identity)
- Personal profile
- Age
- Sex
- Height
- Weight
- BMI
- Skin tone
- Ancestry
- Hair color

- Genomic reference
- Manifest reference

This means **every user in MedGuardian should have their own Ontomorph Digital Twin**, rather than just a standard user profile.

2. Health Events

The platform manages medical events.

Examples:

- Fever
- Headache
- Surgery
- Diagnosis
- Medication
- Vaccination
- Allergies

APIs include:

- Create event
- Delete event
- Emergency card
- Event conflicts

For MedGuardian, every symptom conversation can become a Health Event.

3. Hidden Events

Patients can hide sensitive health records.

Useful for:

- Mental health
- HIV status
- Sensitive diagnoses

This supports patient privacy.

4. Biomarker Trends

One of the strongest features.

Track biomarkers such as:

- Blood glucose
- Blood pressure
- Cholesterol
- Heart rate
- HbA1c
- Kidney function

The API analyzes trends over time.

Instead of just showing today's values, it can reveal whether a patient's health is improving or deteriorating.

5. Alert Rules

Developers can create health alert rules.

Example:

IF Blood Sugar > 180

Notify Patient

Or:

IF Blood Pressure > 180/120

Emergency Alert

It can also evaluate those rules automatically.

This fits perfectly with MedGuardian's emergency detection.

6. Provider Events

Healthcare providers can access patient data with permission.

Features include:

- Provider event management
- Clinical summaries
- Twin lookup by DID
- Addenda to records

This opens the door for doctor-facing dashboards.

7. Secondary Findings

This is genomics-focused.

Supports workflows for:

- Secondary findings
- Genetic counselling referrals
- Patient education acknowledgement
- Clinical disclosure

This is an advanced feature that could be highlighted if your project touches genetic health.

8. Simulations

A dedicated simulation module is listed.

Although the uploaded page doesn't expand the endpoints, it indicates Ontomorph supports simulation capabilities.

Potential uses:

- Disease progression
- Medication response
- Lifestyle impact
- Risk prediction

This could become one of your differentiators.

9. Snapshots

Save a patient's health state at a point in time.

Useful for:

- Before treatment
 - After treatment
 - Comparing health over time
-

10. FHIR Support

FHIR (Fast Healthcare Interoperability Resources) is the global healthcare data standard.

Ontomorph supports FHIR and can seed twins from FHIR bundles.

Benefits:

- Import hospital records
 - Exchange data with hospitals
 - Integrate with healthcare systems
 - Standardized medical records
-

11. Clinical Decision Support (CDSS)

A dedicated CDSS module is listed.

This suggests the platform is designed to support evidence-based clinical recommendations.

Possible uses:

- Treatment guidance
 - Drug interaction support
 - Clinical recommendations
-

12. Analytics

Analytics endpoints indicate support for health data analysis.

Examples:

- Population trends
 - Disease statistics
 - Patient insights
-

13. Insights

A separate Insights module suggests AI-driven or derived health insights beyond raw data.

This is ideal for:

- Personalized recommendations
 - Preventive guidance
 - Health scoring
-

14. Health Module

A dedicated Health module is listed, likely providing platform health services or health-related operations.

15. Metrics

Designed for tracking measurements over time.

Examples:

- Weight
 - BMI
 - Heart rate
 - Temperature
-

16. Provider Simulations

A provider-focused simulation module is available.

Potential use:

Doctors can test treatment scenarios before applying them.

17. Provider APIs

Separate APIs specifically for clinicians.

This supports professional workflows while keeping patient-owned data central.

18. Clinical Mappings

Maps clinical concepts and terminologies.

Useful for:

- ICD
- SNOMED
- LOINC

- Standardized healthcare data
-

19. FHIR Export

Export patient records in the FHIR standard.

Useful for interoperability with hospitals and other healthcare systems.

20. Temporary Access

Patients can grant temporary access to healthcare professionals.

This reinforces the platform's patient-owned data model.

Official SDKs

The documentation also lists official developer resources:

- [ontomorph-core](#)
- [@ontomorph/dtp-sdk](#)
- [@ontomorph/holon-client](#)
- [@ontomorph/holon-types](#)

These SDKs should be your primary integration path if you're building with JavaScript or TypeScript.

What This Means for MedGuardian AI

Your original idea becomes significantly stronger if you **build around the Digital Twin** rather than around a chatbot.

A stronger architecture would be:
